

# Python Datatypes

int & float datatypes

# About Me

My name is Amrik Bhadra

I am a FY student

I am from Computer Department

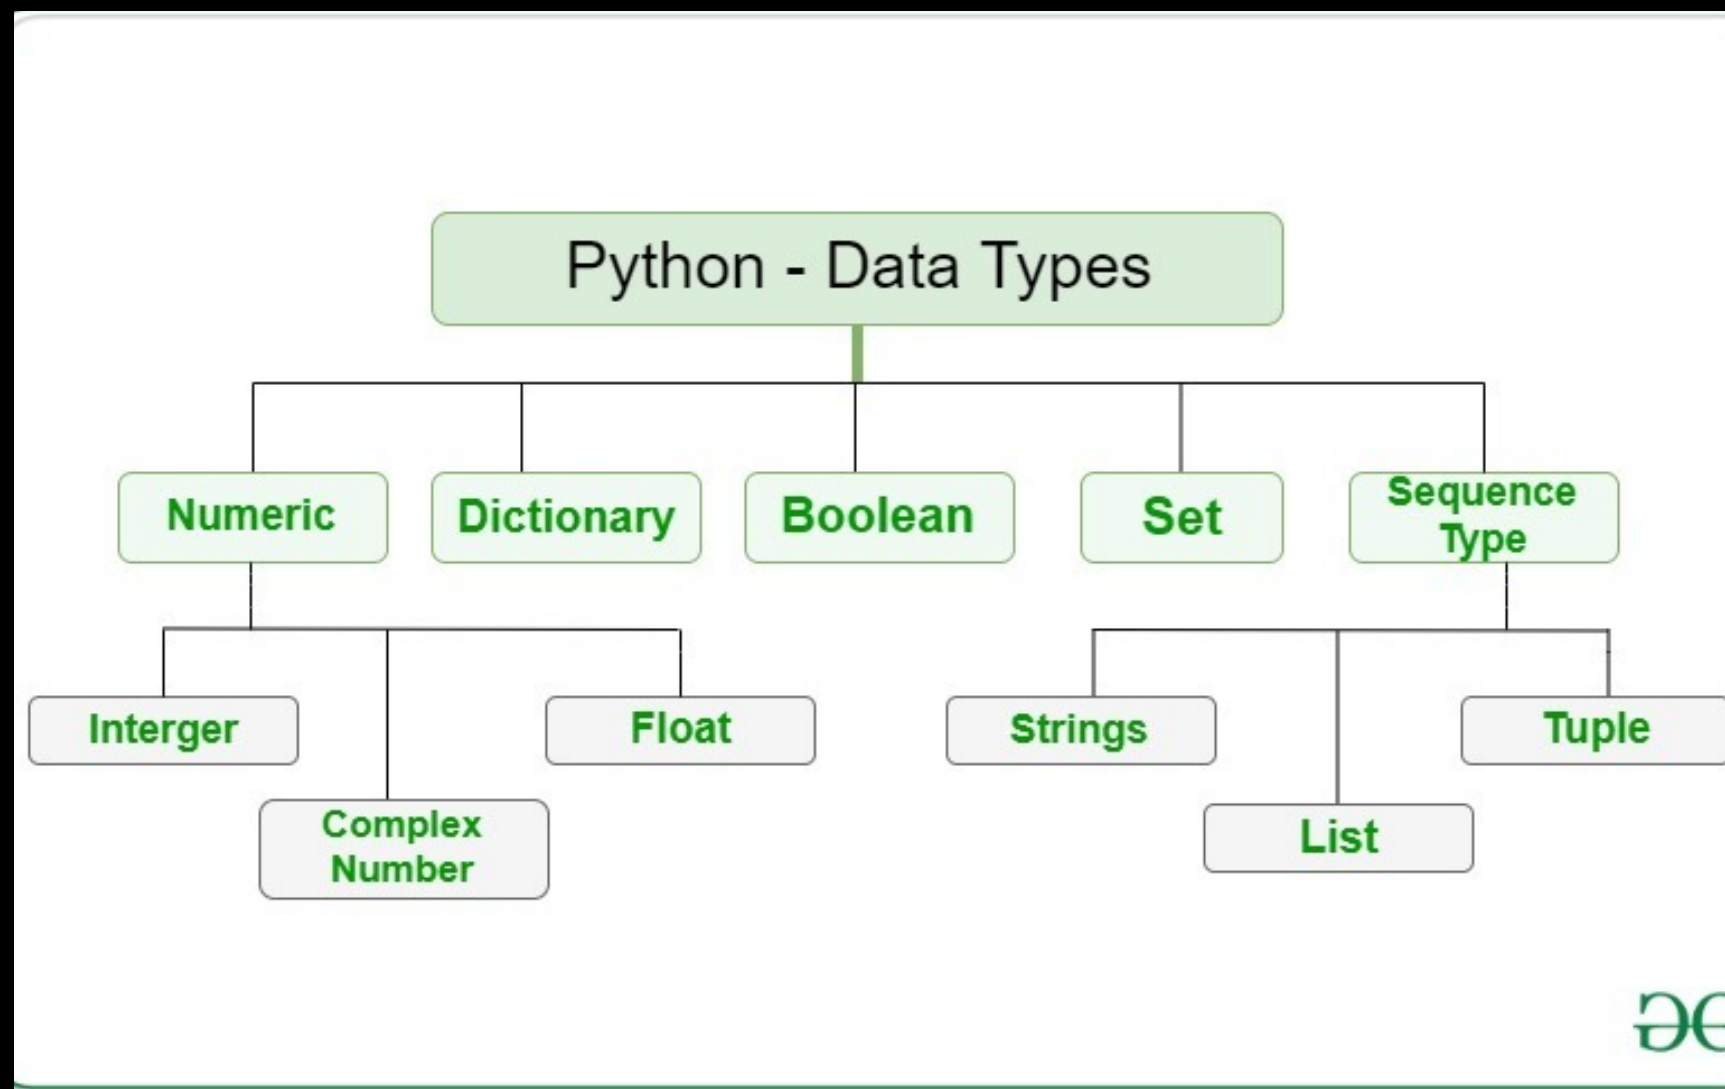

Roll No.: 203

PRN No.: 202201040021

# What are Datatypes?

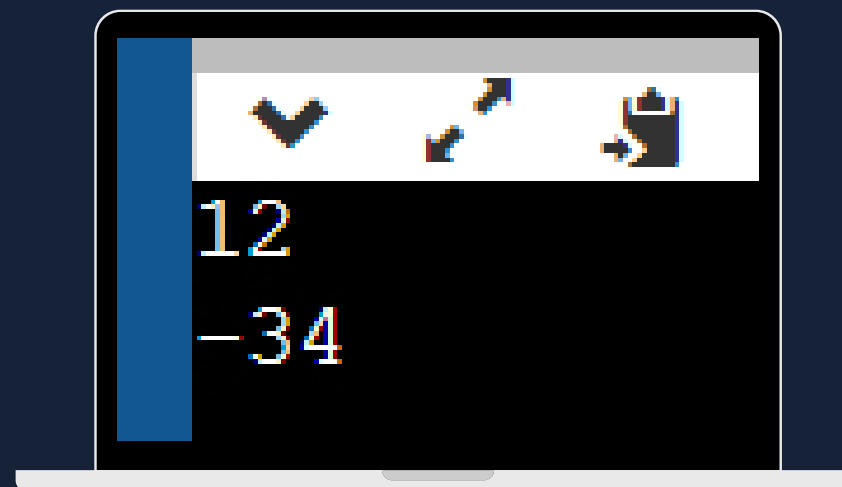

- Data types are the **classification** or **categorization** of data items
- It represents the **kind of value** we store in a variable

# Integer Datatype

- This value is represented by `int` class
- It contains positive or negative whole numbers (without fractions or decimals)

```
1 # integer datatype
2
3 a = 12
4 b = -34
5 print(a)
6 print(b)
```

# Float Datatype

- This value is represented by float class
- It is real number with a floating point representation

```
1 # float datatype
2
3 a = 1.25
4 b = -3.89
5 print(a)
6 print(b)
```

```
1.25
-3.89
```

# type() Function

**type()** method returns class type of the argument(object) passed as parameter in Python

```
1 #type() function
2
3 a = 12
4 b = 3.4
5 print(type(a))
6 print(type(b))
```

```
<class 'int'>
<class 'float'>
```

# Summary.

- Datatypes tells about the **type of data** we are using
- Types of Datatypes: **Numeric** (integer, float, complex), **dictionary**, **set**, **boolean**, **sequence type** (tuple, list, string)
- Integer datatype consists of **positive or negative whole numbers**, without any decimals
- Float datatypes consists of **decimal numbers**
- Integer datatype is represented by `< class 'int' >`
- Float datatype is represented by `< class 'float' >`
- **type()** function is used to display the type of data used

THANK YOU
